EDEM

Docker

September 2021

Agenda

1. Microservice Architecture
2. Containers
3. Docker
4. Docker Compose
5. Kubernetes

1

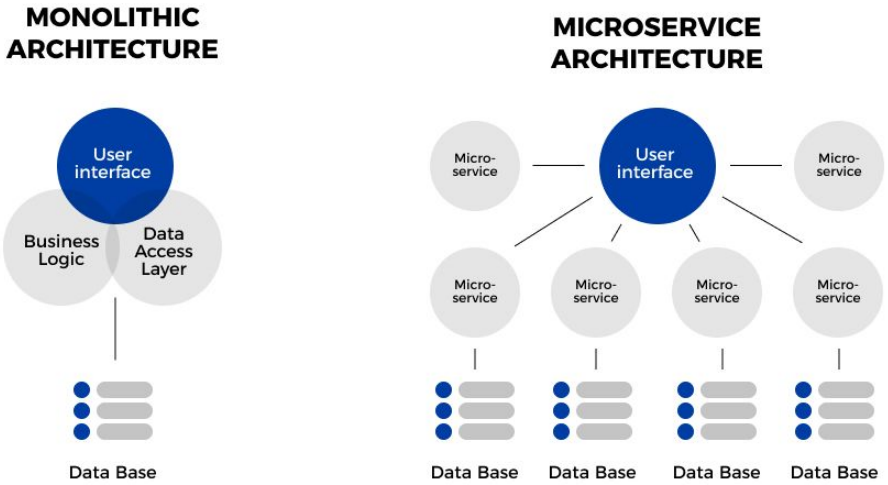
Microservice Architecture

Microservices

- Microservice Architecture is an architectural style that structures an application as a collection of services that are
  - Highly maintainable and testable
  - Loosely coupled
  - Independently deployable
  - Organized around business capabilities
  - Owned by a small team

- The microservice architecture enables the rapid, frequent and reliable delivery of large, complex applications
  - It also enables an organization to evolve its technology stack

Microservice Architecture



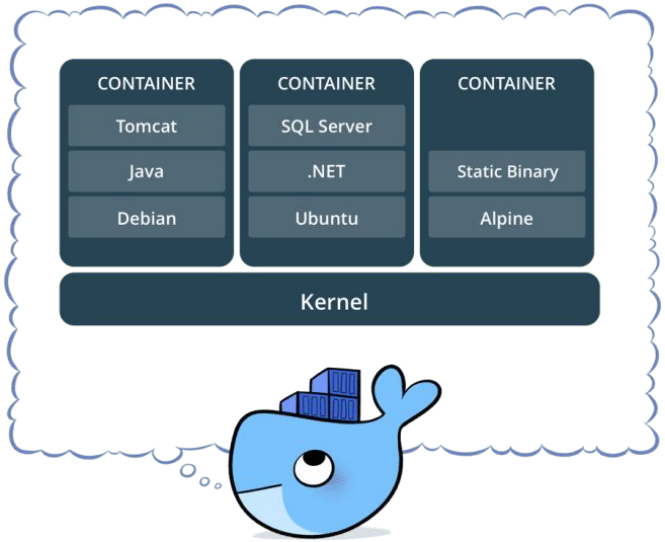
- Developer issues:
  - Minor code changes require full re-compile and re-test
  - Application becomes single point of failure
  - Application is difficult to scale

- Microservice:
  - Break application into separate operations
  - Make the app independently, scalable, stateless, highly available by design

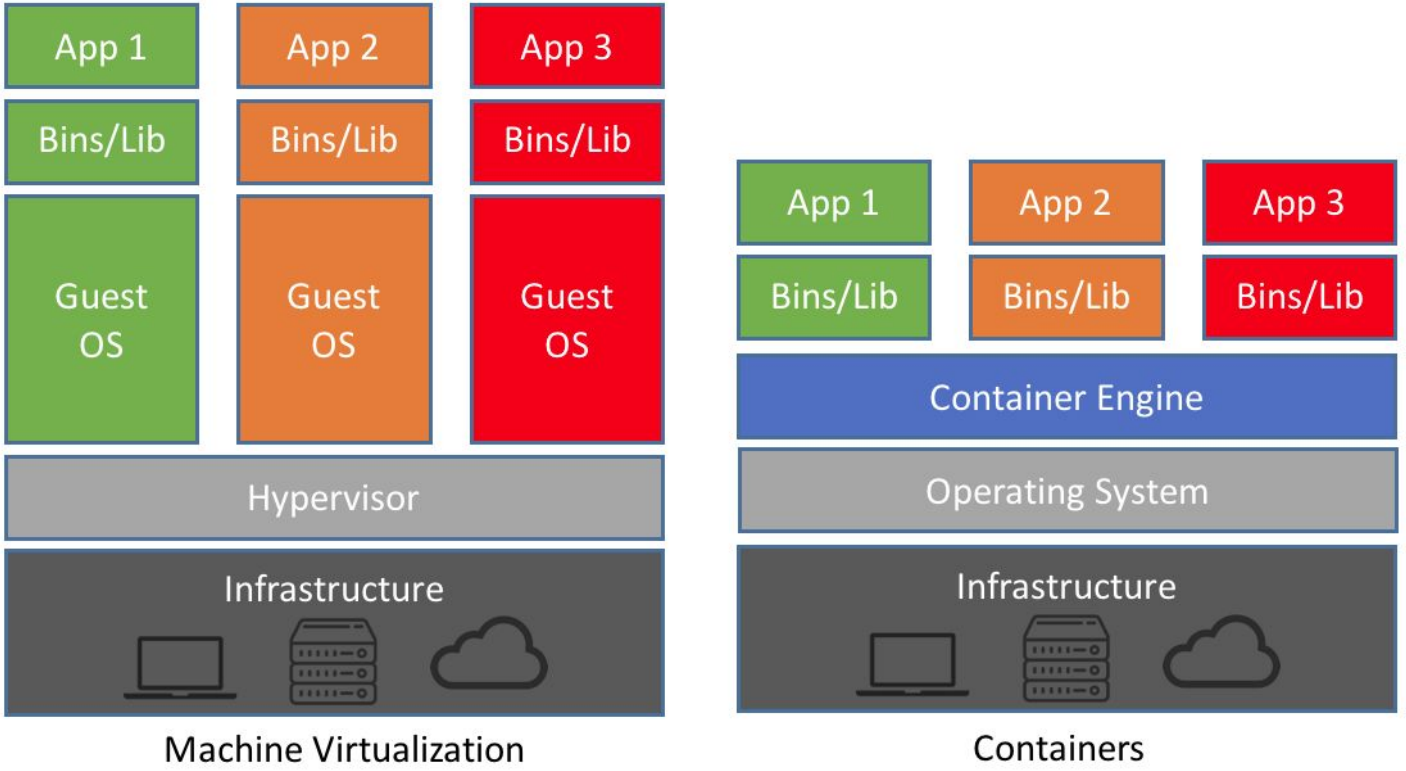
2 Containers

What is a Container?

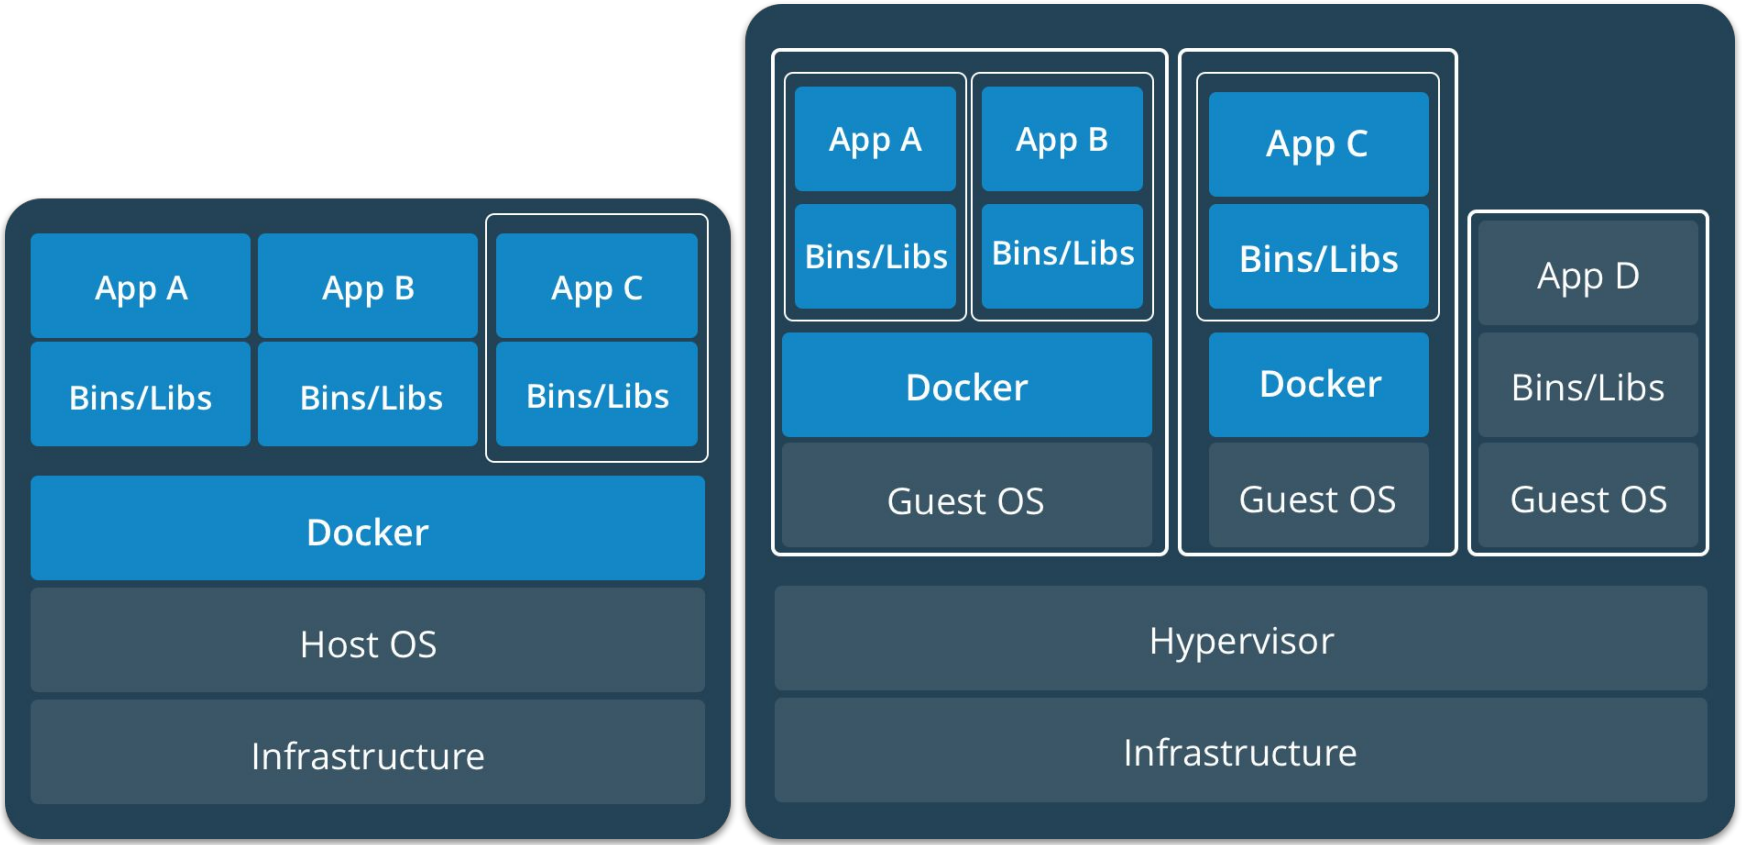
- Standardized packaging for software and dependencies
- Isolate apps from each other
- Share the same OS Kernel
- Works with all major Linux and Windows Server



Containers vs. VMs



Containers & VMs together

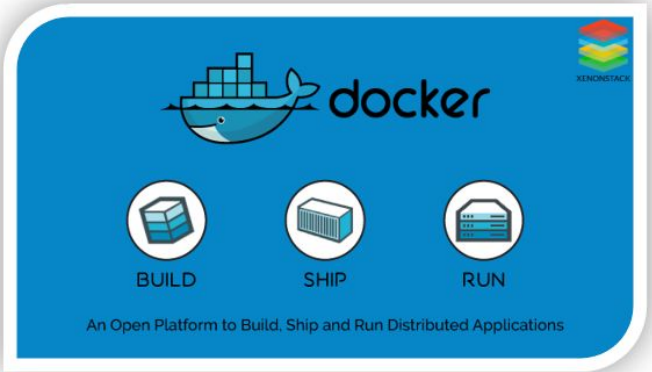


Containers & VMs together

3 Docker

Docker

- Docker is an open platform for developing, shipping, and running containerized applications
- With Docker, you can manage your infrastructure in the same way you manage your applications
- No OS to boot → Applications online in seconds



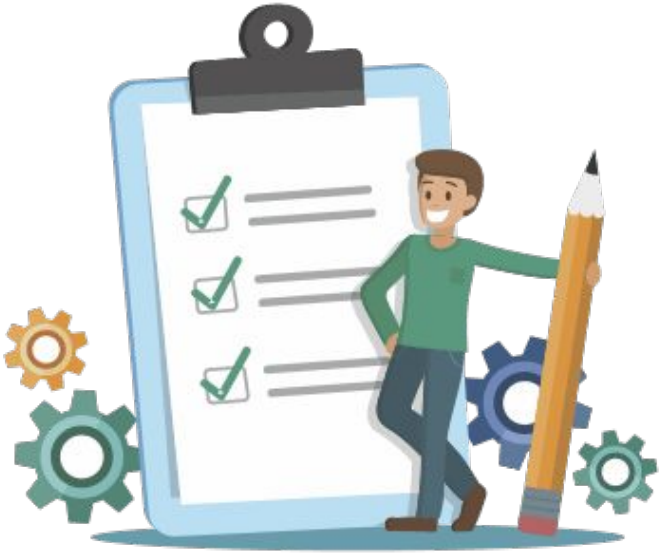
Hands-on

- Docker in your laptop
  - Windows Users (Windows 10 Enterprise & pro & home):

    https://docs.docker.com/desktop/windows/install/
  - Mac Users

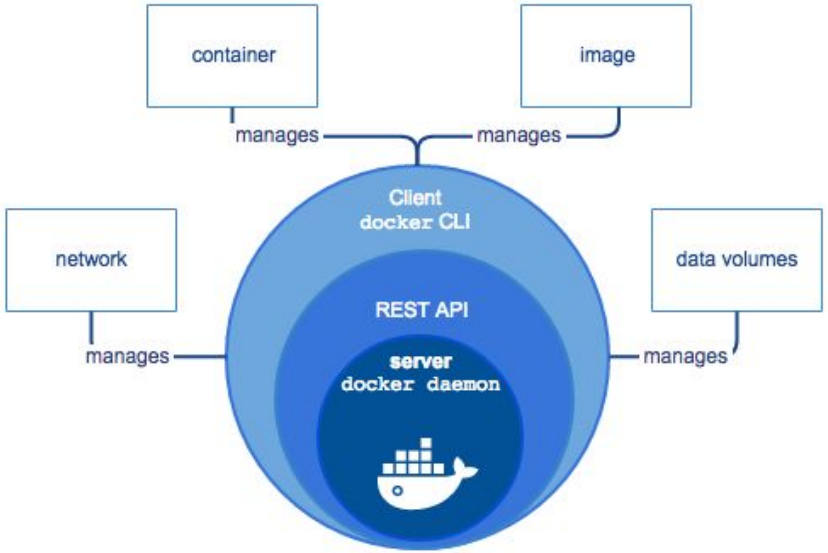
    https://docs.docker.com/desktop/mac/install/
  - Ubuntu Users

    https://docs.docker.com/engine/install/ubuntu/



Docker Engine

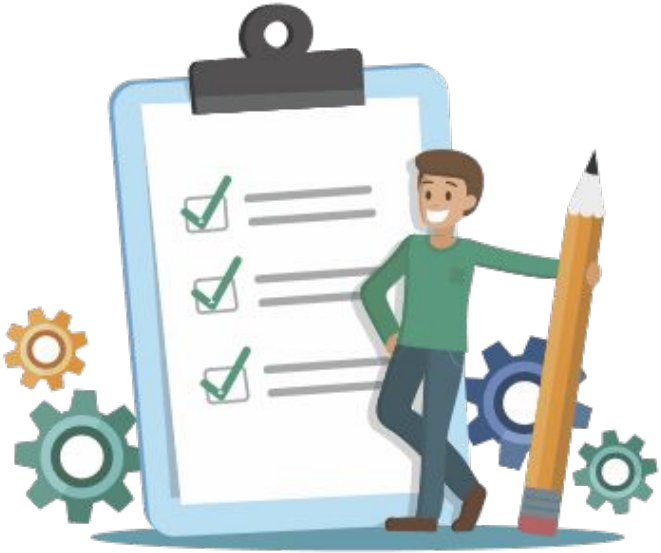
- Docker Engine is a client-server application with these major components:
  - Server
  - REST API
  - Command Line Interface (CLI)



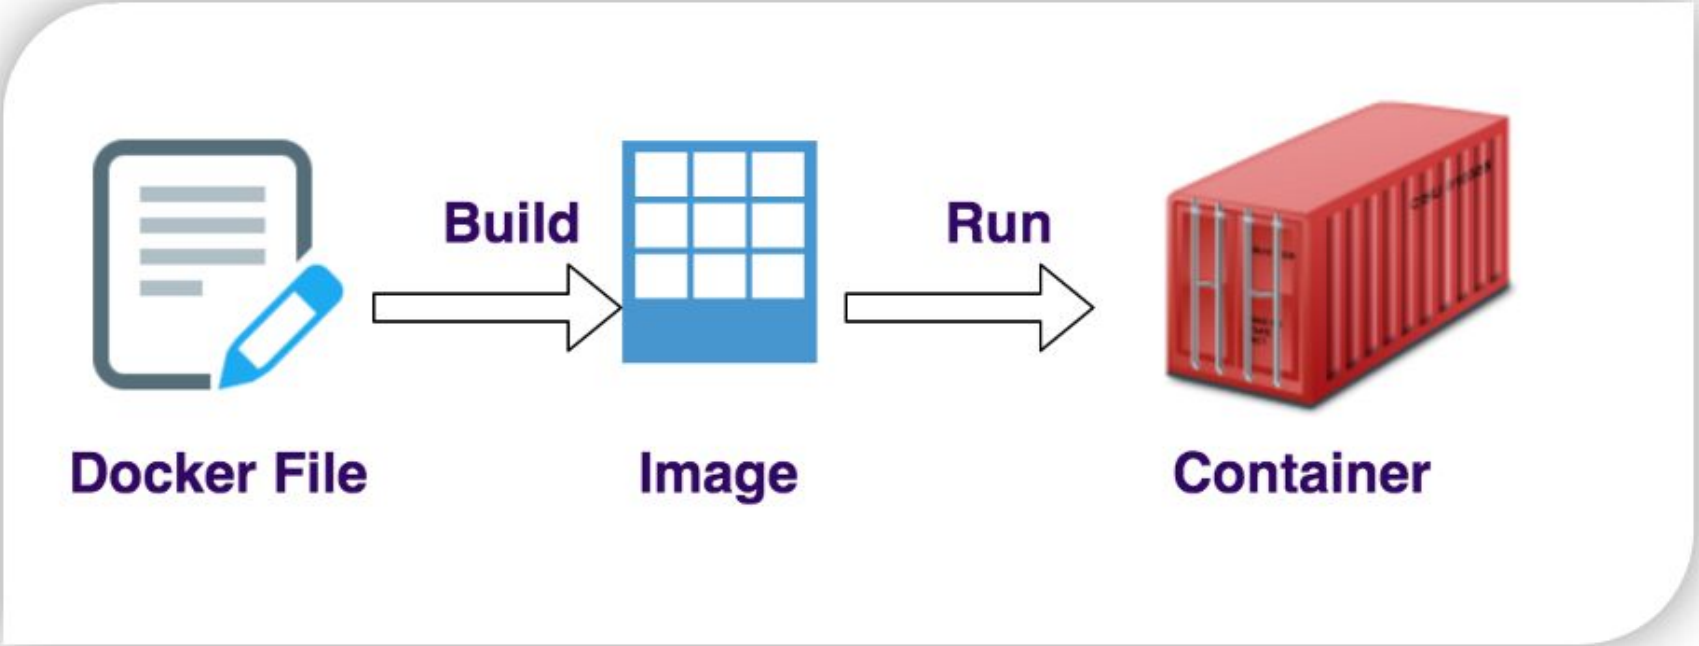
Hands-on

- Docker Google Cloud:
  - Create an **VM instance** with the following features:
    - Zone: us-central1-a
    - Machine: e2-micro
    - OS: Container optimized OS
    - Allow HTTP/HTTPS
  - $ docker version
  - $ docker run -dp 80:80 docker/getting-started
  - Your browser: http://[VM-IP]

- Execute the same instructions in your local machine (Optional)

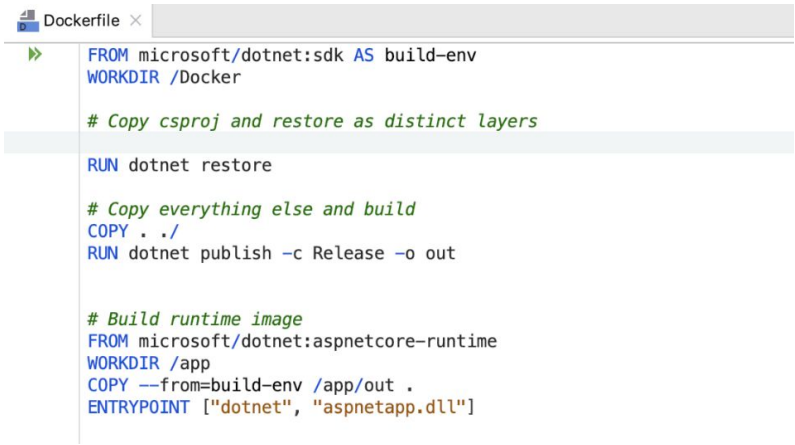


Docker Concepts



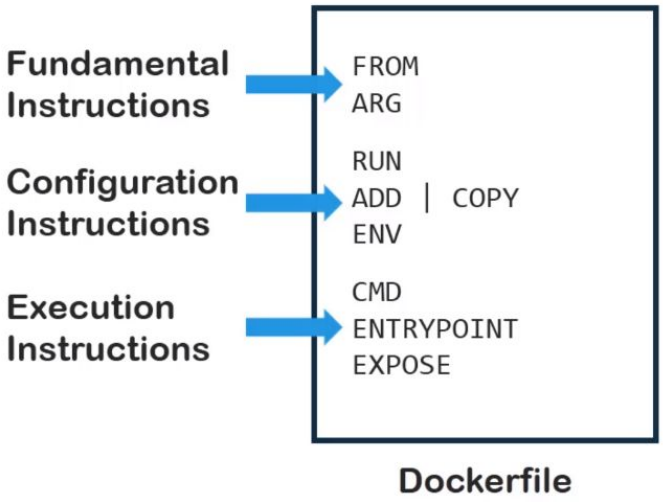
Docker File

- A DockerFile is a text document that contains all the commands a user could call on the command line to assemble an image
  - You can consider DockerFile as blueprint of Docker Image
- DockerFile as a sequential set of instruction for Docker Engine
  - Order of sequence is important!!
  - Each instruction creates a layer
  - A stack of such sequenced layers managed by a filesystem becomes a docker image
  - Layers can be cached and reused by Docker
- Primary way to interacting with Docker



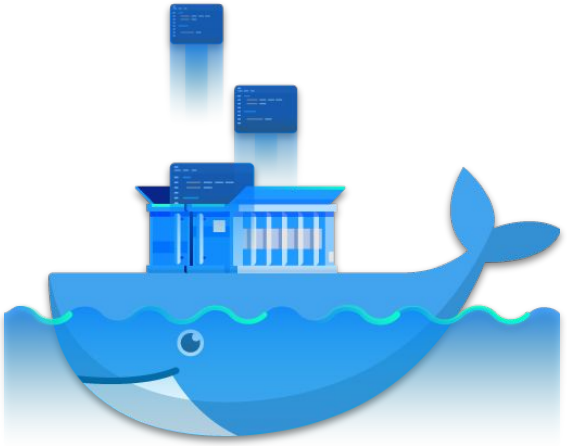
Docker File Structure

- It's a file with no extension called "Dockerfile"
- The instructions can be generally divided into three categories:
  - Fundamental
  - Configuration
  - Execution



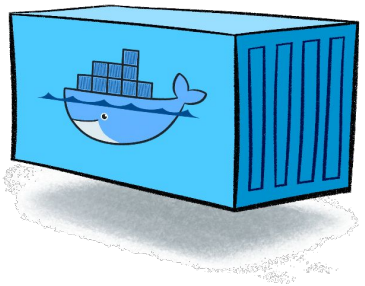
Docker Image

- A stack of multiple layers created from DockerFile instructions
- Recognized by name or Image ID
- The are pushed to and can be pulled from Docker Hub



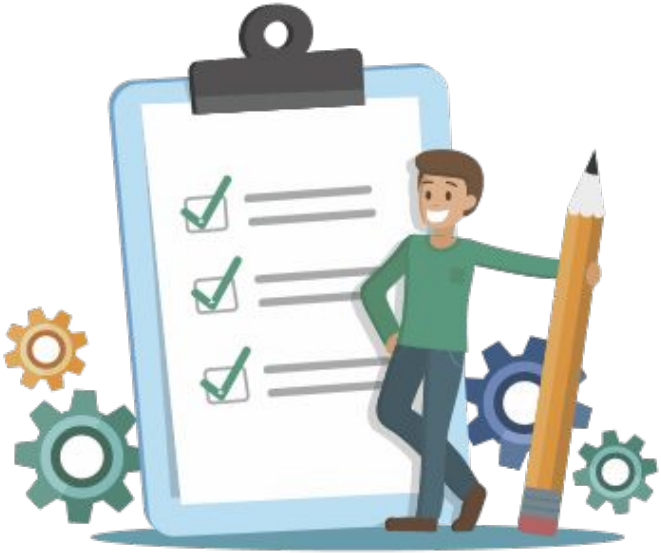
Docker Container

- Running instance of a Docker Image
- Provides similar isolation to VMs but lighter!
- Adds writable layer on top of image layers and works on it
- Can talk to other containers like processes in Linux
- Provide resources to an image



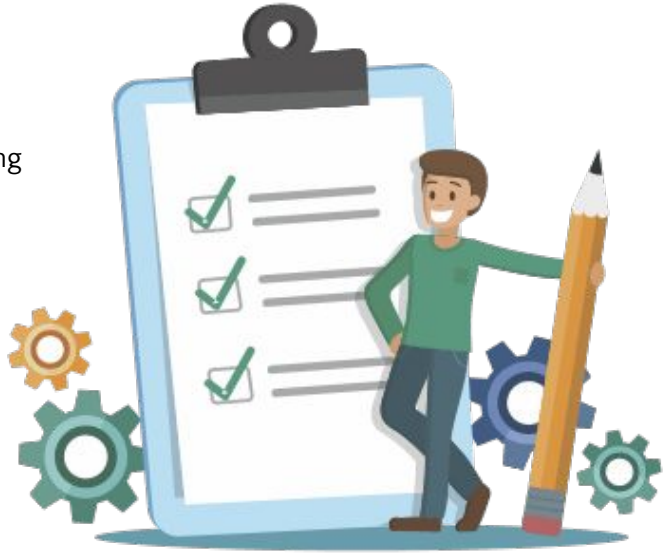
Hands-on

- **Exercise 1**
  - Create a new DockerFile
  - $ docker build -t first_edem_img .
  - $ docker images



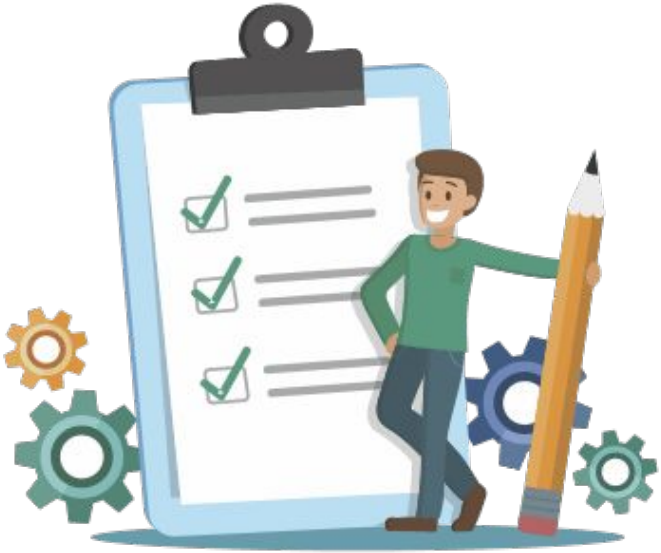
Hands-on

- **Exercise 2**
  - Create a new DockerFile
  - $ docker build -t second_edem_img .
  - $ docker images
  - $ docker run -itd --name cont_second_edem second_edem_img
  - $ docker ps -a
  - $ docker exec -it cont_second_edem bash



Hands-on

- **Exercise 3**
  - Create a new DockerFile
  - $ docker build -t third_edem_img .
  - $ docker images
  - $ docker run -itd --name cont_third_edem -p 8080:80 third_edem_img
  - $ docker ps -a
  - Using your browser, go to this URL: http://localhost:8080

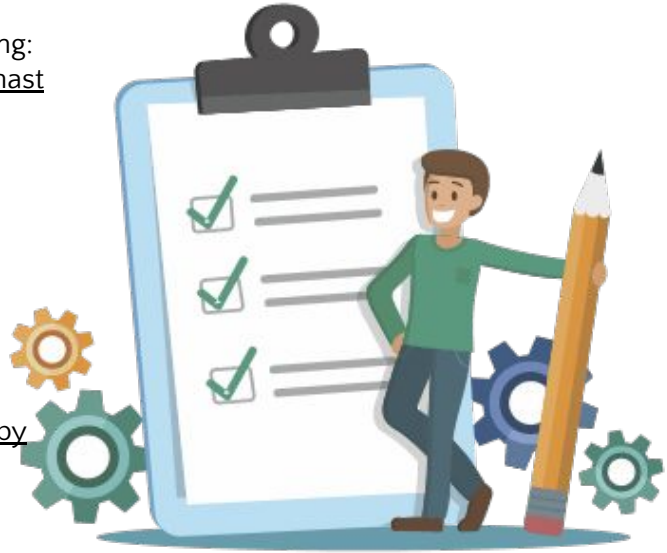


Hands-on

- **Exercise 4**
  - Create a new file called “index.html” which contains the following:
    - https://raw.githubusercontent.com/masfworld/edem/master/index.html

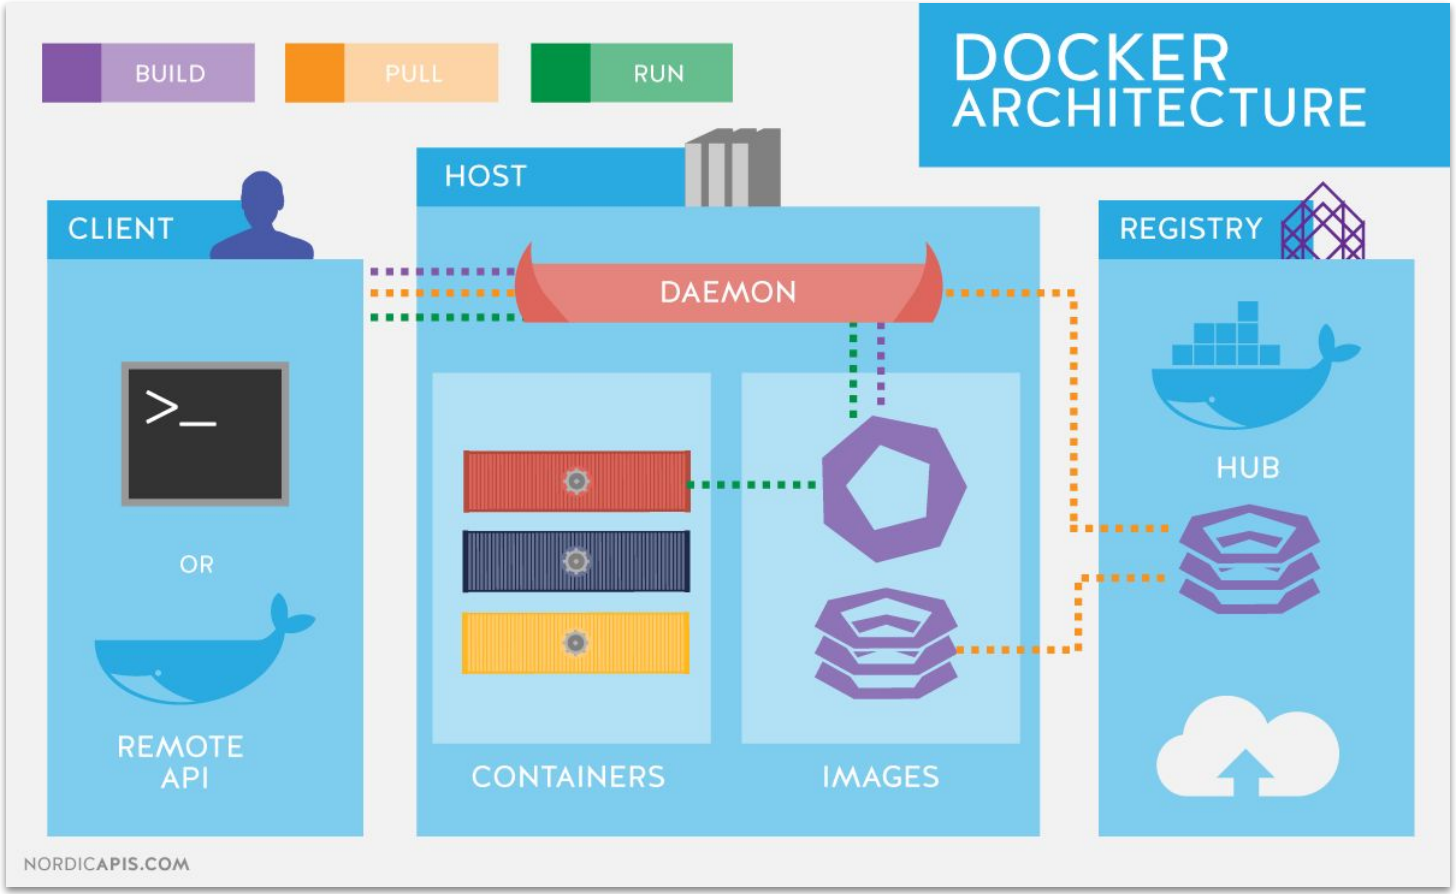
```
<p>Tu primer párrafo.</p>
<p>Tu segundo párrafo.</p>
<p>Un enunciado.
<br> EDEM.</p>
```

  - Modify Dockerfile from Demo 3 to COPY file “index.html” into “/var/www/html”
    - https://docs.docker.com/engine/reference/builder/#copy
  - Dockerfile → https://raw.githubusercontent.com/masfworld/edem/master/DockerFile
  - Generate a container with the previous web page



Docker Registry

- The Registry is a stateless, highly scalable server side application that stores and lets you distribute Docker images
  - Fully own your images distribution pipeline
  - Locally or using Docker Hub



BUILD
PULL
RUN
DOCKER ARCHITECTURE
HOST

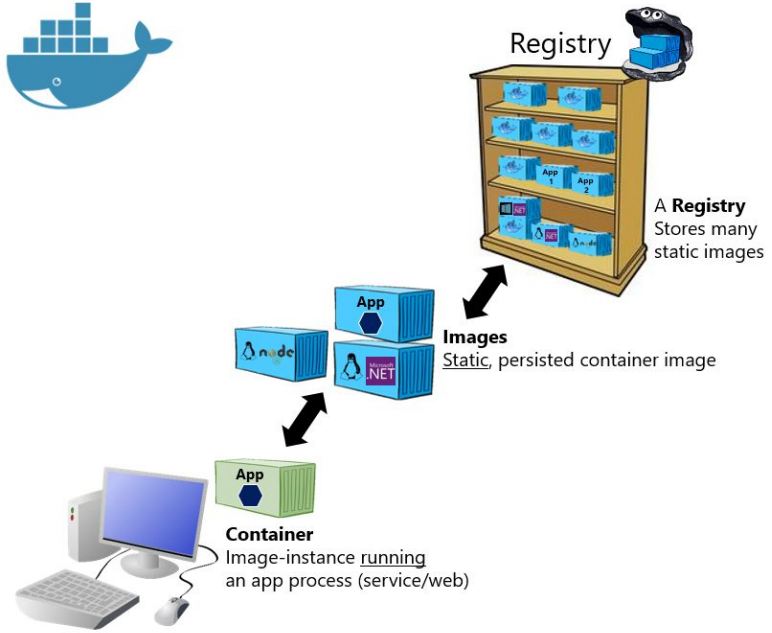
REMOTE API
CONTAINERS
IMAGES
NORDICAPIS.COM

Basic taxonomy in Docker



On-premises
('n' private organizations)

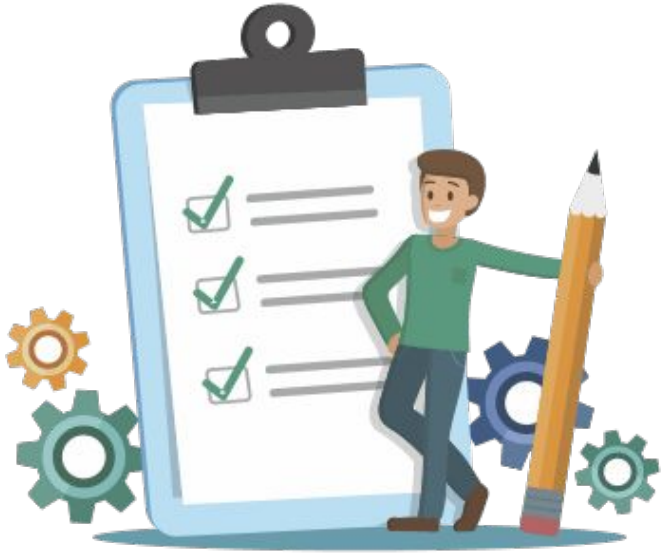
- **Hosted Docker Registry**
- **Docker Trusted Registry on-prem.**

Public Cloud
(specific vendors)

- **Docker Hub Registry**
- Docker Trusted Registry on-cloud
- **Azure Container Registry**
- AWS Container Registry
- Google Container Registry
- Quay Registry
- Other Cloud

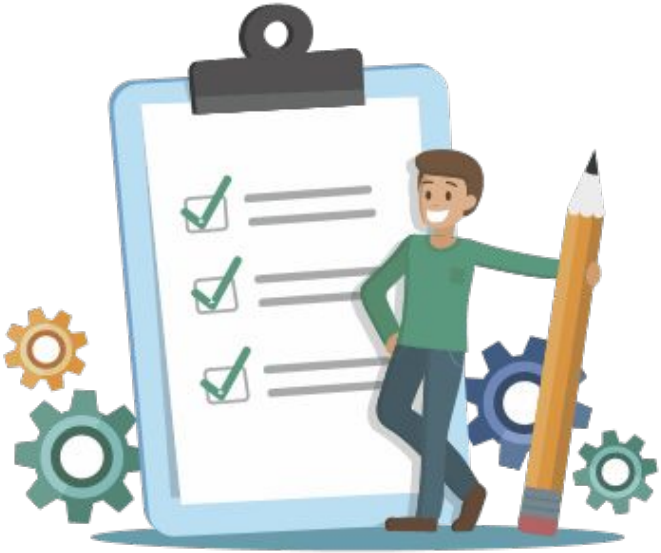
Hands-on

- **Exercise 5**
  - Stop all containers
  - Remove second last image
    - $ docker image rm third_edem_img
    - Any issue?
    - Remove all containers and test again
  - Remove all images except *fourth_edem_img*



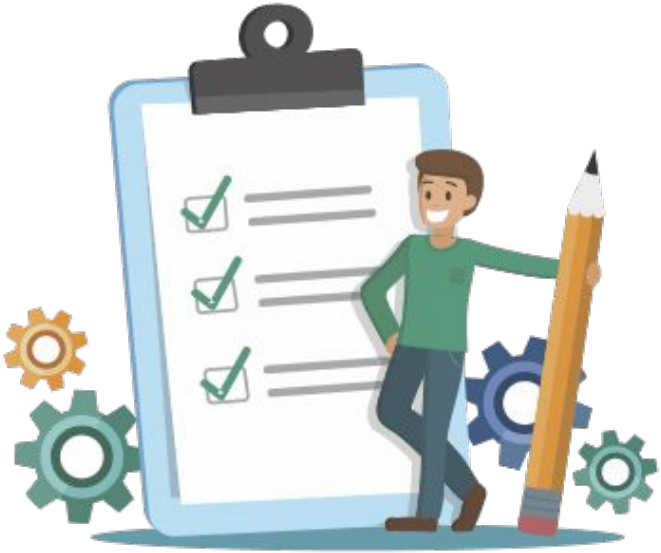
Hands-on

- **Exercise 6**
  - Pull wordpress image from Docker Hub
    https://hub.docker.com/_/wordpress
  - Run a container with Wordpress.
    - We want to access port 8080



Hands-on

- **Exercise 7**
  - Convert web page container into image
    - Execute Container from Exercise 4
    - The name of the container should be something like “cont_exercise_7”
  - $ docker ps -a
  - Add new line in “/var/www/html/index.html”
    - $ docker exec -it cont_exercise_7 bash
    - $ cd /var/www/html
    - $ echo “ my_name ” >> ./index.html
    - $ cat index.html
  - $ docker commit cont_exercise_7 cont_fourth_edem_img_newline:latest
  - $ docker login --username=[Dockerid]
  - $ docker tag [image_id] [Dockerid]/myfirstimage:latest
  - $ docker push [Dockerid]/myfirstimage

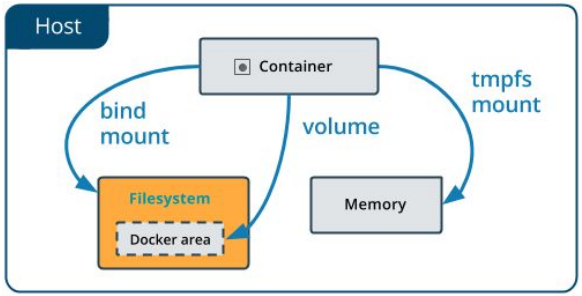


Docker Volume

- What happens to the data if a container crash o removed?
  - Data could be lost!!!

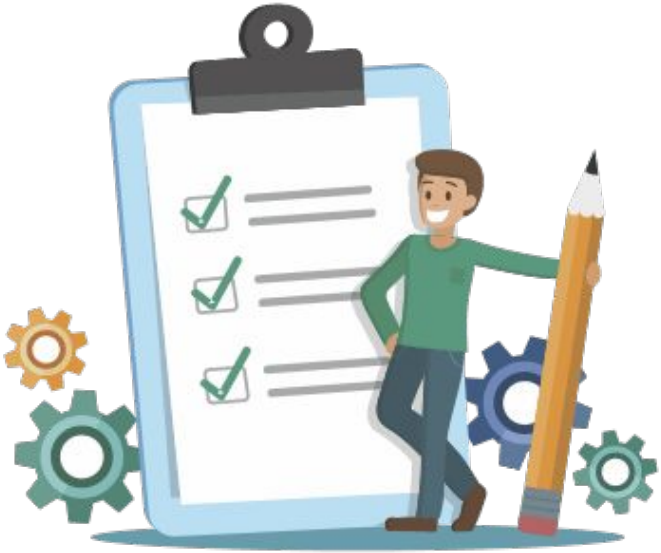
- Docker has two options for containers to store files in the host machine:
  - Volumes
  - Bind mounts

- Volumes have the following advantages:
  - Easier to back up or migrate
  - Managed using Docker CLI
  - More safely shared among multiple containers
  - Isolated from the host file system



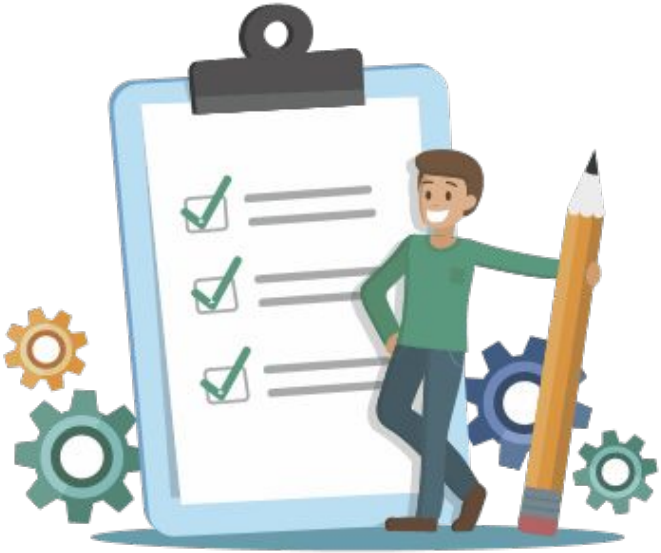
Hands-on

- **Exercise 8**
  - $ docker volume create my-vol
  - $ docker volume ls
  - $ docker volume inspect my-vol
  - $ docker run -d --name volume_test --mount source=my-vol,target=/app [DockerId]/myfirstimage
  - $ docker exec -it volume_test bash



Hands-on

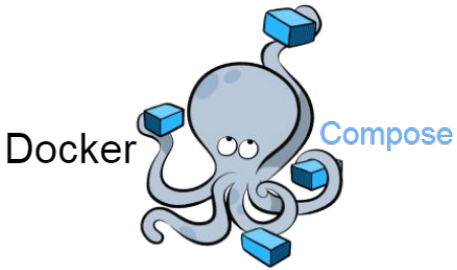
- **Exercise 9**
  - Remove all containers
  - Remove all images except wordpress and exercise 4 image



4 Docker Compose

Docker Compose

- Compose is a tool for defining and running complex applications with docker
- Without Docker Compose, multiple DockerFiles will be needed for a full or complex application
  - Separate files for front-end, back-end…
- With Docker Compose, you can define a multi-container application in a single file
- Usually the file is called “docker-compose.yml”

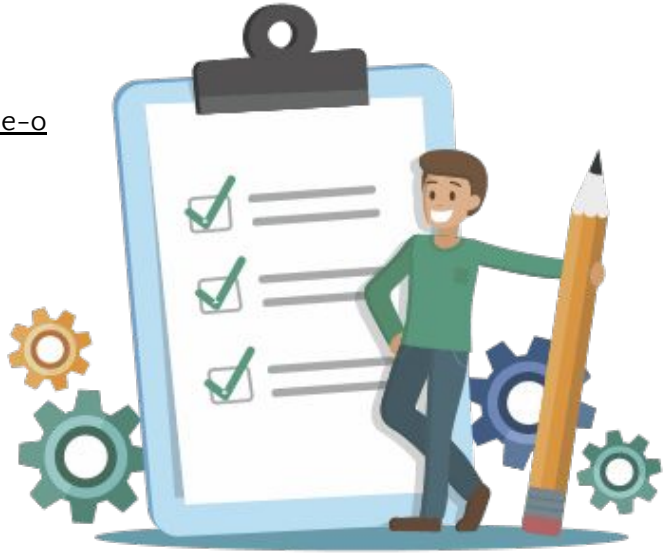


Docker Compose

```yaml
version: '3'
services:
    app:
        build:
          context: ./app
          dockerfile: Dockerfile
        volumes:
          - /datastore/app:/app
        ports:
            - "5000:5000"
            - "9001:9001"
            - "80:80"
        depends_on:
            - influxdb
    influxdb:
        image: influxdb
        volumes:
          - /datastore/influx:/var/lib/influxdb
        ports:
            - "8086:8086"
    grafana:
        build:
          context: ./grafana
          dockerfile: Dockerfile
        volumes:
          - /datastore/grafana:/var/lib/grafana
        ports:
            - "3000:3000"
```

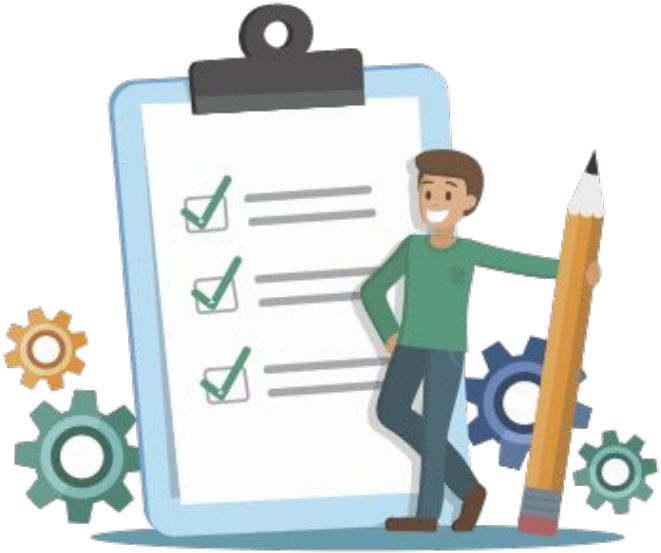
Hands-on

- Install Docker compose in GCP VM
  - https://cloud.google.com/community/tutorials/docker-compose-on-container-optimized-os



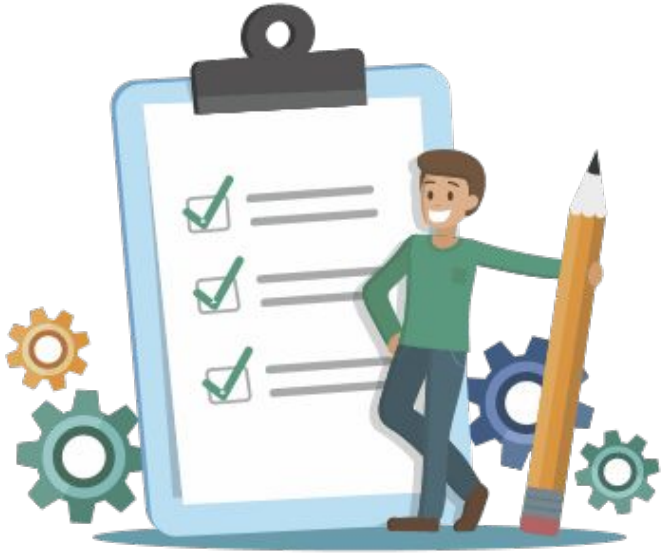
Hands-on

- **Exercise 10**
  - Create a docker compose file
    - Use this file:
    - https://docs.docker.com/compose/wordpress/
  - $ docker compose up -d



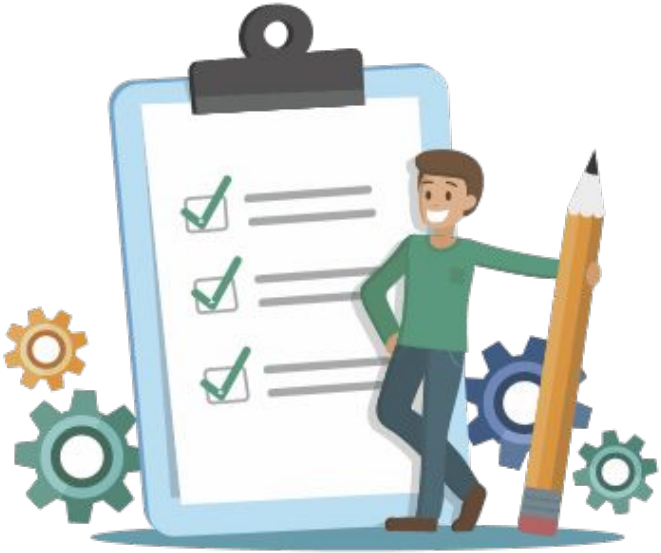
Hands-on

- **Exercise 11**
  - Add Ubuntu con Nginx from exercise 4 into the previous docker-compose file
  - Execute this docker-compose again with new changes



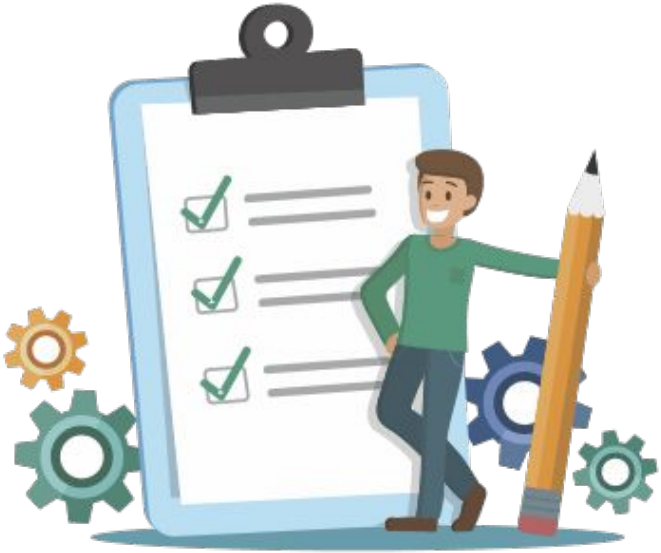
Hands-on

- **Exercise 12**
  - Remove all containers
  - Remove all images
  - Remove all volumes



Hands-on

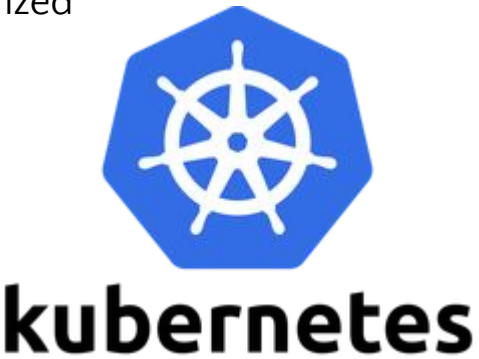
- **Exercise 13**
  - Install Jupyter using Docker



5 Kubernetes

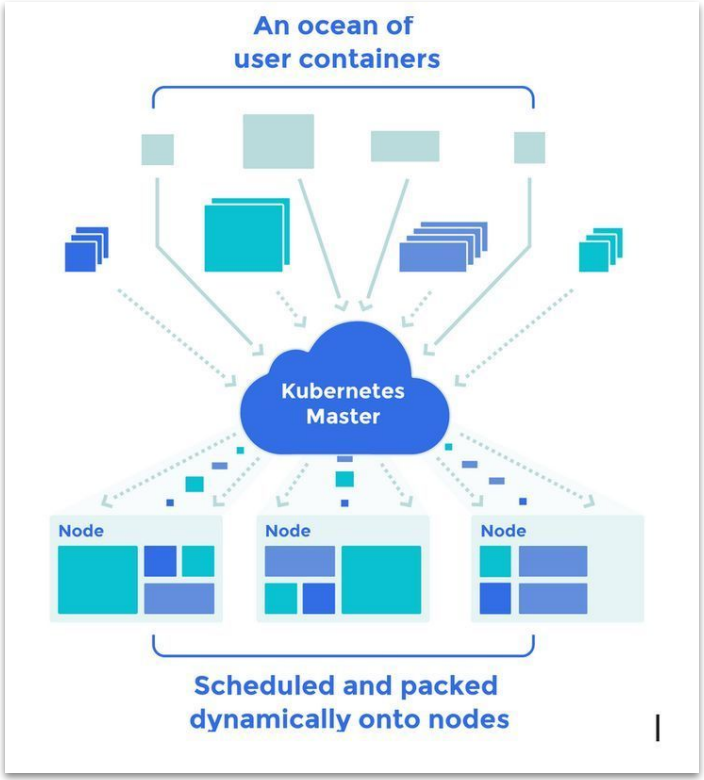
Kubernetes

- Large and small software companies deploying thousands of container instances daily
  - How can we manage this complexity?
- Originally developed by Google.
- Kubernetes is an open-source container orchestration platform designed to automate the deployment, scaling, and management of containerized applications
- Kubernetes makes it easy to deploy and operate applications in a microsevice architecture



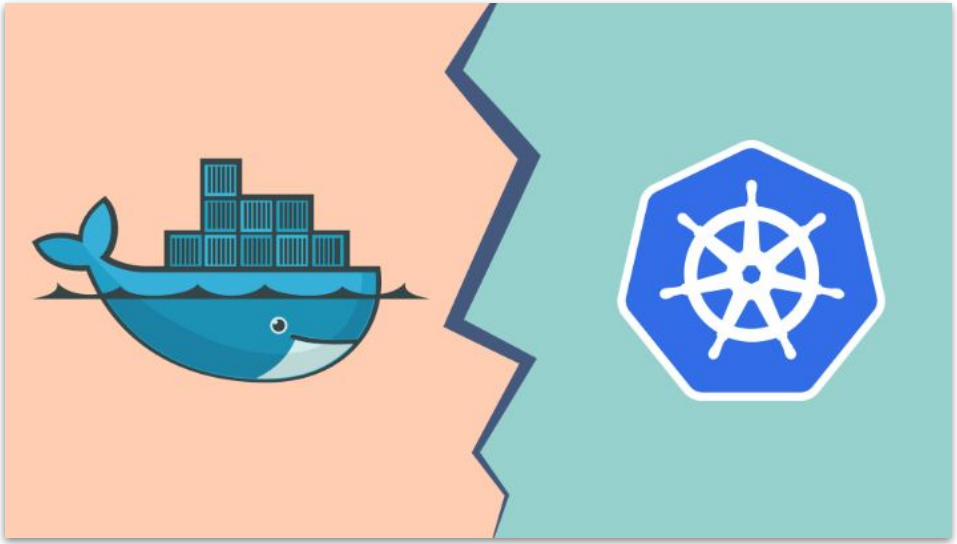
Kubernetes

- Features:
  - Controlling resource consumption by application or team
  - Evenly spreading application load across a host infrastructure
  - Automatically load balancing requests across the different instances of an application
  - Monitoring resource consumption and resource limits
  - Moving an application instance from one host to another
  - Automatically leveraging additional resources made available when a new host is added

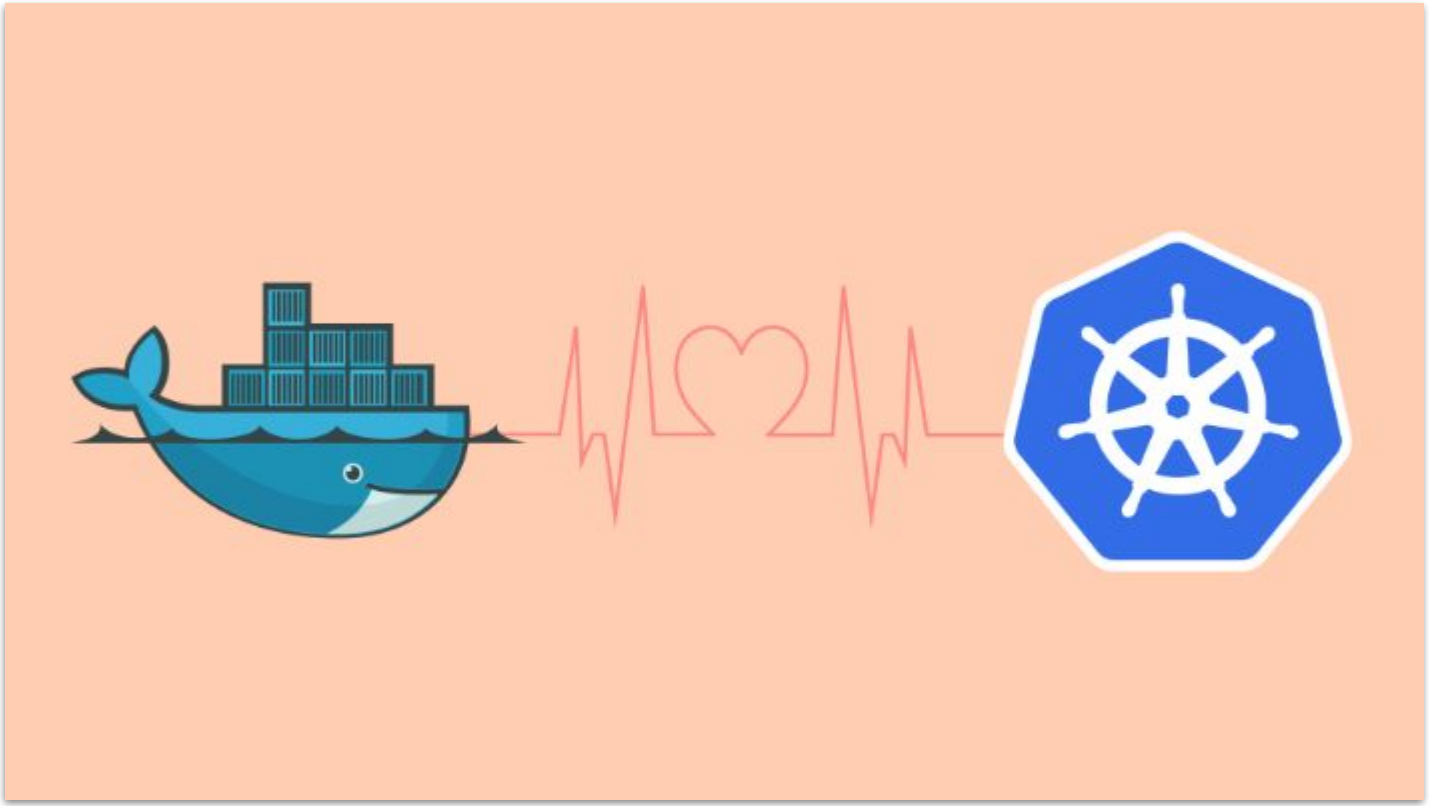


Kubernetes - Docker

- Docker is used to isolate your application into containers
- Kubernetes, on the other hand, is a container scheduler. It's used to deploy and scale your application



Kubernetes - Docker



Thanks!
